Pointwise Bounds and Blow-up for Systems of Semilinear Parabolic Inequalities and Nonlinear Heat Potential Estimates

Marius Ghergu[*] Steven D. Taliaferro[†][‡]

Abstract

We study the behavior for t small and positive of $C^{2,1}$ nonnegative solutions $u(x,t)$ and $v(x,t)$ of the system

$$\begin{aligned} 0 \le u_t - \Delta u \le v^\lambda \\ 0 \le v_t - \Delta v \le u^\sigma \end{aligned} \qquad \text{in } \Omega\times(0,1),$$

where λ and σ are nonnegative constants and Ω is an open subset of $\mathbb{R}^n$, $n\ge 1$. We provide optimal conditions on λ and σ such that solutions of this system satisfy pointwise bounds in compact subsets of Ω as $t\to 0^+$. Our approach relies on new pointwise bounds for nonlinear heat potentials which are the parabolic analog of similar bounds for nonlinear Riesz potentials.

2010 Mathematics Subject Classification. 35B09, 35B33, 35B44, 35B45, 35K40, 35R45.

Keywords: Parabolic system; Partial differential inequalities; Heat potential estimate; Pointwise bound; Blow-up.

1 Introduction

In this paper we study the behavior for t small and positive of $C^{2,1}$ nonnegative solutions $u(x,t)$ and $v(x,t)$ of the system

$$\begin{aligned} 0 \le u_t - \Delta u \le v^\lambda \\ 0 \le v_t - \Delta v \le u^\sigma \end{aligned} \qquad \text{in } \Omega\times(0,1), \tag{1.1}$$

where λ and σ are nonnegative constants and Ω is an open subset of $\mathbb{R}^n$, $n\ge 1$. More precisely, we consider the following question.

Question 1. For which nonnegative constants λ and σ do there exist continuous functions $h_1, h_2 : (0,1)\to(0,\infty)$ such that for all compact subsets K of Ω and for all $C^{2,1}$ nonnegative solutions $u(x,t)$ and $v(x,t)$ of the system (1.1) we have

$$\max_{x\in K} u(x,t) = O(h_1(t)) \qquad \text{as } t\to 0^+ \tag{1.2}$$

$$\max_{x\in K} v(x,t)) = O(h_2(t)) \qquad \text{as } t\to 0^+ \tag{1.3}$$

and what are the optimal such h_1 and h_2 when they exist?

We call a function h_1 (resp. h_2) with the above properties a pointwise bound in compact subsets for u (resp. v) as $t\to 0^+$.

Remark 1.1. Let

$$\Phi(x,t) = \begin{cases} \frac{1}{(4\pi t)^{n/2}} e^{-\frac{|x|^2}{4t}} & \text{for } (x,t) \in \mathbb{R}^n \times (0,\infty) \\ 0 & \text{for } (x,t) \in \mathbb{R}^n \times (-\infty, 0] \end{cases} \tag{1.4}$$

be the heat kernel. Since $\Phi_t - \Delta\Phi = 0$ in $\mathbb{R}^n \times (0,\infty)$, the functions $u_0 = v_0 = \Phi$ are always $C^{2,1}$ nonnegative solutions of (1.1). Hence, since $\Phi(0,t) = \frac{1}{(4\pi t)^{n/2}}$, any pointwise bound as $t \to 0^+$ in compact subsets of Ω for nonnegative solutions of (1.1) must be at least as large as $t^{-n/2}$ and whenever $t^{-n/2}$ is such a bound for u (resp. v) it is necessarily optimal. In this case we say that u (resp. v) is *heat bounded* in compact subsets of Ω as $t \to 0^+$.

We shall see that whenever a pointwise bound as $t \to 0^+$ in compact subsets of Ω for nonnegative solutions of (1.1) exists, then u or v (or both) are heat bounded as $t \to 0^+$.

The literature on scalar and systems of parabolic *equations* is quite vast. A good source for this material is the book [11]. However, very little attention has been paid to systems of parabolic *inequalities*, and, as far as we know, all results deal with a very different aspect of these inequalities; namely the nonexistence of global solutions. See for example [3, 4, 10].

Let us mention some of the methods and tools we use to study Question 1. First and most noteworthy of these are some new results for linear and nonlinear heat potentials. To motivate them recall that if $f : \mathbb{R}^n \to \mathbb{R}$, $n \geq 3$, is a nonnegative measurable function, $\alpha \in (0,n)$ is a constant, and

$$\Gamma(x) = \frac{C(n)}{|x|^{n-2}}$$

is a fundamental solution of $-\Delta$ in $\mathbb{R}^n$ then the Riesz potential of f is given by the convolution

$$\Gamma^{\frac{n-\alpha}{n-2}} * f.$$

It has been extensively studied because of its usefulness in potential theory and the study of elliptic PDEs. See for example the books [12, 1, 9]. Three important results concerning the Riesz potential operator, which are relevant to this paper, are Hedberg's inequality [6]; the Hardy-Littlewood-Sobolev inequality (see [12, p. 119]); and estimates for the nonlinear potential

$$\Gamma^{\frac{n-\alpha}{n-2}} * \left(\left(\Gamma^{\frac{n-\beta}{n-2}} * f \right)^{\sigma} \right)$$

first studied in [8]. A crucial tool for the proofs of these results is the celebrated Hardy-Littlewood maximal function inequalities (see [12, p. 5]).

In our study of Question 1 there arises naturally the need to obtain similar results for the convolution

$$\Phi^{\frac{n+2-\alpha}{n}} * f, \tag{1.5}$$

where $f : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$, $n \geq 1$, is a nonnegative measurable function, $\alpha \in (0, n+2)$ is a constant, and Φ is the fundamental solution of the heat operator given by (1.4). These new results for the heat potential operator (1.5) are stated and proved in Section 3 using a modified version of the Hardy-Littlewood maximal function inequalities in which Euclidean balls in $\mathbb{R}^n$ are replaced with heat balls in $\mathbb{R}^n \times \mathbb{R}$.

Two other tools required are a Moser type iteration (see Lemma 4.6) and a representation formula given in Lemma 4.1 for nonnegative super temperatures which is the parabolic analog of the Brezis-Lions representation formula [2] for nonnegative superharmonic functions.

2 Statement of results

In this section we state our results for Question 1. We can assume without loss of generality that $\sigma \le \lambda$.

If λ and σ are nonnegative constants satisfying $\sigma \le \lambda$ then (λ, σ) belongs to one of the following four pointwise disjoint subsets of the $\lambda\sigma$-plane:

$$\begin{aligned}
A &:= \left\{(\lambda,\sigma) : \, 0 \le \sigma \le \lambda \le \frac{n+2}{n}\right\} \\
B &:= \left\{(\lambda,\sigma) : \, \lambda > \frac{n+2}{n} \quad \text{and} \quad 0 \le \sigma < \frac{2}{n} + \frac{n+2}{n\lambda}\right\} \\
C &:= \left\{(\lambda,\sigma) : \, \lambda > \frac{n+2}{n} \quad \text{and} \quad \frac{2}{n} + \frac{n+2}{n\lambda} < \sigma \le \lambda\right\} \\
D &:= \left\{(\lambda,\sigma) : \, \lambda > \frac{n+2}{n} \quad \text{and} \quad \sigma = \frac{2}{n} + \frac{n+2}{n\lambda}\right\}.
\end{aligned}$$

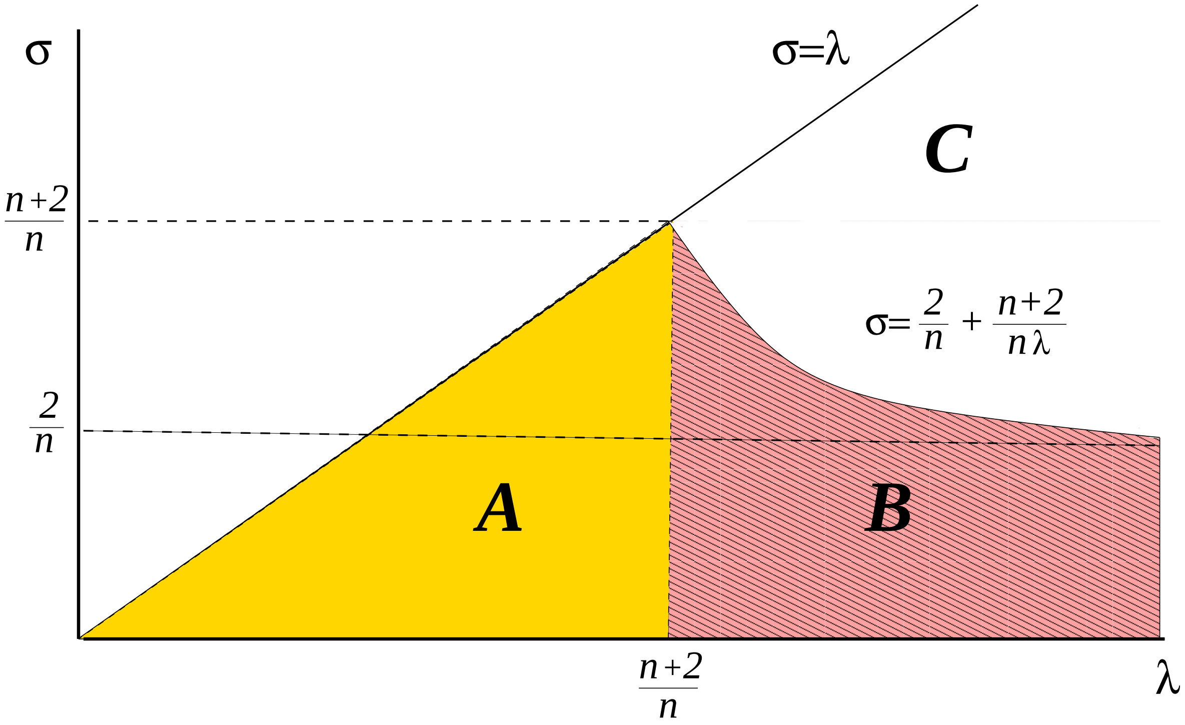

Figure 1: Graph of regions A, B and C.

Note that A, B and C are two dimensional regions in the $\lambda\sigma$-plane whereas D is the curve separating B and C. (See Figure 1.)

In this section we give a complete answer to Question 1 when $(\lambda, \sigma) \in A \cup B \cup C$. The following theorem deals with the case that $(\lambda, \sigma) \in A$.

Theorem 2.1. *Suppose* $u(x,t)$ *and* $v(x,t)$ *are* $C^{2,1}$ *nonnegative solutions of the system*

$$\left.\begin{aligned} 0 \le u_t - \Delta u &\le \left(v + \left(\frac{1}{\sqrt{t}}\right)^n\right)^\lambda \\ 0 \le v_t - \Delta v &\le \left(u + \left(\frac{1}{\sqrt{t}}\right)^n\right)^\sigma \end{aligned}\right\} \quad \text{in } \Omega \times (0,1), \tag{2.1}$$

where the constants λ *and* σ *satisfy*

$$0 \le \sigma \le \lambda \le \frac{n+2}{n} \tag{2.2}$$

and Ω *is an open subset of* $\mathbb{R}^n$, $n \ge 1$. *Then both* u *and* v *are heat bounded in compact subsets of* Ω *as* $t \to 0^+$, *that is, for each compact subset* K *of* Ω *we have*

$$\max_{x \in K} u(x,t) = O\left(\left(\frac{1}{\sqrt{t}}\right)^n\right) \qquad \text{as } t \to 0^+ \tag{2.3}$$

and

$$\max_{x \in K} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}}\right)^n\right) \qquad \text{as } t \to 0^+. \tag{2.4}$$

By Remark 1.1, the bounds (2.3) and (2.4) are optimal.

The following two theorems deal with the case that $(\lambda, \sigma) \in B$.

Theorem 2.2. *Suppose* $u(x,t)$ *and* $v(x,t)$ *are* $C^{2,1}$ *nonnegative solutions of the system* (2.1) *where the constants* λ *and* σ *satisfy*

$$\lambda > \frac{n+2}{n} \quad \text{and} \quad \sigma < \frac{2}{n} + \frac{n+2}{n\lambda} \tag{2.5}$$

and Ω *is an open subset of* $\mathbb{R}^n$, $n \ge 1$. *Then for each compact subset* K *of* Ω *we have*

$$\max_{x \in K} u(x,t) = o\left(\left(\frac{1}{\sqrt{t}}\right)^{\frac{n^2\lambda}{n+2}}\right) \qquad \text{as } t \to 0^+ \tag{2.6}$$

and

$$\max_{x \in K} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}}\right)^n\right) \qquad \text{as } t \to 0^+. \tag{2.7}$$

By the following theorem the bounds (2.6) and (2.7) for u and v in Theorem 2.2 are optimal.

Theorem 2.3. *Suppose* λ *and* σ *satisfy* (2.5) *and* $\varphi : (0,1) \to (0,1)$ *is a continuous function satisfying* $\lim_{t\to 0^+} \varphi(t) = 0$. *Then there exist* C^∞ *positive solutions* $u(x,t)$ *and* $v(x,t)$ *of the system*

$$\left.\begin{aligned} 0 \le u_t - \Delta u &\le v^\lambda \\ 0 \le v_t - \Delta v &\le u^\sigma \end{aligned}\right\} \quad \text{in } (\mathbb{R}^n \times \mathbb{R}) \setminus \{(0,0)\}, \ n \ge 1, \tag{2.8}$$

such that

$$u(0,t) \ne O\left(\varphi(t)\left(\frac{1}{\sqrt{t}}\right)^{\frac{n^2\lambda}{n+2}}\right) \qquad \text{as } t \to 0^+ \tag{2.9}$$

and

$$\liminf_{t \to 0^+} v(0,t)t^{n/2} > 0. \tag{2.10}$$

The following theorem deals with the case that $(\lambda, \sigma) \in C$. In this case there exist pointwise bounds for neither u nor v.

Theorem 2.4. *Suppose λ and σ are constants satisfying*

$$\lambda > \frac{n+2}{n} \quad \text{and} \quad \frac{2}{n} + \frac{n+2}{n\lambda} < \sigma \leq \lambda. \tag{2.11}$$

Let $\varphi : (0,1) \to (0,\infty)$ be a continuous function satisfying

$$\lim_{t \to 0^+} \varphi(t) = \infty.$$

Then there exist C^∞ solutions $u(x,t)$ and $v(x,t)$ of the system

$$\left.\begin{aligned} &0 \leq u_t - \Delta u \leq v^\lambda \\ &0 \leq v_t - \Delta v \leq u^\sigma \\ &u > 1,\ v > 1 \end{aligned}\right\} \qquad \text{in} \ \ (\mathbb{R}^n \times \mathbb{R}) \setminus \{(0,0)\},\ n \geq 1, \tag{2.12}$$

such that

$$u(0,t) \neq O(\varphi(t)) \quad \text{as } t \to 0^+ \tag{2.13}$$

and

$$v(0,t) \neq O(\varphi(t)) \quad \text{as } t \to 0^+. \tag{2.14}$$

The following theorem can be viewed as the limiting case of Theorem 2.2 as $\lambda \to \infty$.

Theorem 2.5. *Suppose $u(x,t)$ and $v(x,t)$ are $C^{2,1}$ nonnegative solutions of the system*

$$\begin{aligned} &0 \leq u_t - \Delta u \\ &0 \leq v_t - \Delta v \leq \left(u + \left(\frac{1}{\sqrt{t}} \right)^n \right)^\sigma \end{aligned} \qquad \text{in } \Omega \times (0,1),$$

where $\sigma < 2/n$ and Ω is an open subset of $\mathbb{R}^n$, $n \geq 1$. Then v is heat bounded in compact subsets of Ω as $t \to 0^+$, that is, for each compact subset K of Ω we have

$$\max_{x \in K} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^n \right) \qquad \text{as } t \to 0^+. \tag{2.15}$$

By Remark 1.1, the bound (2.15) is optimal.

A consequence of the methods we use to prove the results in this section is the following simple, optimal, and apparently unknown result. The proof is, however, nontrivial being based on the representation formula in Lemma 4.1.

Theorem 2.6. *Suppose u is a $C^{2,1}$ nonnegative solution of*

$$0 \leq u_t - \Delta u \leq \left(\frac{1}{\sqrt{t}} \right)^\gamma \qquad \text{in } \Omega \times (0,1),$$

where $\gamma \in \mathbb{R}$ and Ω is an open subset of $\mathbb{R}^n$, $n \geq 1$. Then for each compact subset K of Ω we have

$$\max_{x \in K} u(x,t) = \begin{cases} o\left(\left(\frac{1}{\sqrt{t}} \right)^{\gamma \frac{n}{n+2}} \right) & \text{if } \gamma > n+2 \\ O\left(\left(\frac{1}{\sqrt{t}} \right)^{n} \right) & \text{if } \gamma \leq n+2 \end{cases} \qquad \text{as } t \to 0^+.$$

In the next section we shall derive the analog of Hedberg's inequality for heat potentials as well as estimates for nonlinear heat potential which are crucial tools of our approach. More preliminary results are provided in Section 4. The proof of the main results will be given in Section 5.

3 Hedberg's inequality for heat potentials and nonlinear heat potential estimates

We define $J_\alpha : \mathbb{R}^n \times \mathbb{R} \to [0,\infty)$ for $n \geq 1$ and $0 < \alpha < n+2$ by

$$J_\alpha(x,t) = \Phi(x,t)^{\frac{n+2-\alpha}{n}} \tag{3.1}$$

where Φ is the heat kernel (1.4). If $f : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ is a nonnegative measurable function then we call the convolution $J_\alpha * f : \mathbb{R}^n \times \mathbb{R} \to [0,\infty]$, given by

$$(J_\alpha * f)(x,t) = \iint_{\mathbb{R}^n \times \mathbb{R}} \Phi(x-y,t-s)^{\frac{n+2-\alpha}{n}} f(y,s)\,dy\,ds, \tag{3.2}$$

a heat potential of f.

The main result in this section is the following theorem which gives estimates for the nonlinear potential $J_\alpha * ((J_\beta * f)^\sigma)$. This potential is the nonlinear heat potential analog of the nonlinear Riesz potential first studied by Maz'ya and Havin [8]. See also [9, Chapter 10].

Theorem 3.1. *Suppose*

$$\alpha, \beta \in (0, n+2), \quad \sigma > \frac{\alpha}{n+2-\beta}, \quad \textit{and} \quad 1 \leq r < \frac{(n+2)\sigma}{\alpha + \beta\sigma}. \tag{3.3}$$

Then there exists a constant $C = C(n,\alpha,\beta,\sigma,r) > 0$ such that for all nonnegative measurable functions $f : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$, $n \geq 1$, we have

$$\|J_\alpha * ((J_\beta * f)^\sigma)\|_{L^\infty(\mathbb{R}^n\times\mathbb{R})} \leq C \|f\|_{L^r(\mathbb{R}^n\times\mathbb{R})}^{\frac{(\alpha+\beta\sigma)r}{n+2}} \|f\|_{L^\infty(\mathbb{R}^n\times\mathbb{R})}^{\frac{\sigma(n+2-\beta r)-\alpha r}{n+2}}.$$

For the proof of Theorem 3.1, we will need three auxiliary results of independent interest. Namely, (i) a heat potential analog of Hedberg's Riesz potential inequality; (ii) a heat ball analog of the Hardy-Littlewood maximal function inequality; and (iii) a new Sobolev inequality for heat potentials. These three results are stated below in Theorems 3.2, 3.3, and 3.4, respectively.

To precisely state these results we first need some definitions.

If $(x,t) \in \mathbb{R}^n \times \mathbb{R}$, $n \geq 1$ and $r \in [0,\infty]$ then the set

$$E_r(x,t) := \begin{cases} \{(y,s) \in \mathbb{R}^n \times \mathbb{R} : \Phi(x-y,t-s) > \frac{1}{r^n}\} & \text{if } 0 < r < \infty, \\ \{(y,s) \in \mathbb{R}^n \times \mathbb{R} : s < t\} & \text{if } r = \infty, \\ \emptyset & \text{if } r = 0 \end{cases} \tag{3.4}$$

is called a *heat ball.*

Let d be the metric on $\mathbb{R}^n \times \mathbb{R}$ defined by

$$d\left((x,t),(y,s)\right) = \max\left\{|x-y|, \sqrt{|t-s|}\right\}. \tag{3.5}$$

For $(x,t) \in \mathbb{R}^n \times \mathbb{R}$ and $r > 0$ let

$$Q_r(x,t) = \{(y,s) \in \mathbb{R}^n \times \mathbb{R} : d\left((x,t),(y,s)\right) < r\} \tag{3.6}$$

be the open ball in the metric space $(\mathbb{R}^n \times \mathbb{R}, d)$ with center (x,t) and radius r, and let

$$P_r(x,t) = \{(y,s) \in Q_r(x,t) : s < t\} \tag{3.7}$$

be the lower half of $Q_r(x,t)$.

Under the change of variables

$$-r\eta = x-y, \quad -r^2\zeta = t-s, \qquad \text{where } r>0, \tag{3.8}$$

we have

$$\Phi(x-y,t-s) = r^{-n}\Phi(-\eta,-\zeta). \tag{3.9}$$

Thus for $0 \le a < b \le \infty$ and $\beta \in \mathbb{R}$ we find that

$$\iint_{E_{br}(x,t)\setminus E_{ar}(x,t)} \Phi(x-y,t-s)^\beta \, dy\, ds = r^{n+2-n\beta} \iint_{E_b(0,0)\setminus E_a(0,0)} \Phi(-\eta,-\zeta)^\beta \, d\eta\, d\zeta \tag{3.10}$$

and using the fact that

$$\int_{\mathbb{R}^n} \Phi(-\eta,-\zeta)^\beta \, d\eta = \frac{C(\beta,n)}{(-\zeta)^{(\beta-1)n/2}} \quad \text{for } \zeta<0 \text{ and } \beta>0,$$

it is easy to check, for use in (3.10), that

$$\iint_{E_\infty(0,0)\setminus E_1(0,0)} \Phi(-\eta,-\zeta)^\beta \, d\eta\, d\zeta < \infty \quad \left(\text{resp. } \iint_{E_1(0,0)} \Phi(-\eta,-\zeta)^\beta d\eta\, d\zeta < \infty\right) \tag{3.11}$$

if $\beta > \frac{n+2}{n}$ (resp. $\beta < \frac{n+2}{n}$). Clearly

$$|Q_r(x,t)| = r^{n+2}|Q_1(0,0)| \quad \text{and} \quad |P_r(x,t)| = r^{n+2}|P_1(0,0)| \tag{3.12}$$

and taking $\beta = 0 = a$ and $b=1$ in (3.10) we get

$$|E_r(x,t)| = r^{n+2}|E_1(0,0)|. \tag{3.13}$$

Lemma 3.1. *There exists $r_0 = r_0(n) > 0$ such that*

$$E_r(x,t) \subset P_{r_0 r}(x,t) \subset Q_{r_0 r}(x,t) \quad \textit{for all } (x,t)\in\mathbb{R}^n\times\mathbb{R} \textit{ and all } r>0.$$

Proof. Choose $r_0>0$ such that $E_1(0,0)\subset Q_{r_0}(0,0)$. Suppose $r>0$, $(x,t)\in\mathbb{R}^n\times\mathbb{R}$, and

$$(y,s)\in E_r(x,t). \tag{3.14}$$

Then $s<t$ and making the change of variables (3.8) we have (3.9) holds. It follows therefore from the definition of $E_r(x,t)$ and (3.14) that

$$(\eta,\zeta)\in E_1(0,0)\subset Q_{r_0}(0,0).$$

Hence $\max\{|\eta|,\sqrt{-\zeta}\} < r_0$. So

$$d\left((x,t),(y,s)\right) = \max\{|x-y|,\sqrt{t-s}\} = \max\{r|\eta|, r\sqrt{-\zeta}\} < r_0 r.$$

Thus $(y,s)\in Q_{r_0 r}(x,t)$. Hence, since $s<t$, we have $(y,s)\in P_{r_0 r}(x,t)$. □

Lemma 3.2. *Suppose $a>-1$, $b\ge 0$, and $\alpha>0$ are constants and $g:\mathbb{R}^m\to\mathbb{R}$, $m\ge 1$, is a nonnegative measurable function. Then*

$$\frac{\alpha^{a+1}}{a+1}\int_{\mathbb{R}^m} g(x)^{a+b+1}dx = \int_0^\infty \lambda^a \left(\int_{\{g>\lambda/\alpha\}} g(x)^b dx\right) d\lambda. \tag{3.15}$$

Proof.

$$\begin{aligned}
\text{L.H.S. of (3.15)} &= \int_{\mathbb{R}^m} \frac{(\alpha g(x))^{a+1}}{a+1} g(x)^b dx \\
&= \int_{\mathbb{R}^m} \left(\int_0^{\alpha g(x)} \lambda^a d\lambda \right) g(x)^b dx \\
&= \int_{\mathbb{R}^m} \left(\int_0^{\infty} (\chi_{[0,\alpha g(x)]}(\lambda)) \lambda^a d\lambda \right) g(x)^b dx \\
&= \int_0^{\infty} \lambda^a \left(\int_{\mathbb{R}^m} \chi_{[0,\alpha g(x)]}(\lambda) g(x)^b dx \right) d\lambda \\
&= \text{R.H.S. of (3.15).}
\end{aligned}$$

□

The following theorem is the heat potential analog of Hedberg's Riesz potential inequality [6].

Theorem 3.2. *Suppose* $0 < \alpha < n+2$ *and* $1 \le p < \frac{n+2}{\alpha}$ *are constants and* $f : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ *is a nonnegative measurable function. Then*

$$J_\alpha * f(x,t) \le C \|f\|_{L^p(\mathbb{R}^n \times \mathbb{R})}^{\frac{\alpha p}{n+2}} (Mf(x,t))^{1-\frac{\alpha p}{n+2}} \quad \textit{for } (x,t) \in \mathbb{R}^n \times \mathbb{R} \tag{3.16}$$

where $C = C(n, \alpha, p)$ *is a positive constant and*

$$Mf(x,t) = \sup_{r>0} \frac{1}{|E_r(x,t)|} \iint_{E_r(x,t)} f(y,s)\, dy\, ds \tag{3.17}$$

is the heat ball analog of the Hardy-Littlewood maximal function.

Proof. Let $\rho > 0$. Then

$$\begin{aligned}
&\int_0^\rho \frac{1}{r^{n+3-\alpha}} \left(\iint_{E_r(x,t)} f(y,s)\, dy\, ds \right) dr \\
&= \int_0^\rho \left(\iint_{\mathbb{R}^n \times \mathbb{R}} \frac{1}{r^{n+3-\alpha}} \chi_{E_r(x,t)}(y,s) f(y,s)\, dy\, ds \right) dr \\
&= \iint_{\mathbb{R}^n \times \mathbb{R}} \left(\int_0^\rho \frac{1}{r^{n+3-\alpha}} \chi_{E_r(x,t)}(y,s)\, dr \right) f(y,s)\, dy\, ds \\
&= \iint_{E_\rho(x,t)} \left(\int_0^\rho \frac{1}{r^{n+3-\alpha}} \chi_{E_r(x,t)}(y,s)\, dr \right) f(y,s)\, dy\, ds \\
&= \iint_{E_\rho(x,t)} \left(\int_{\frac{1}{\Phi(x-y,t-s)^{1/n}}}^\rho \frac{dr}{r^{n+3-\alpha}} \right) f(y,s)\, dy\, ds \\
&= \frac{1}{n+2-\alpha} \iint_{E_\rho(x,t)} \left(\Phi(x-y,t-s)^{\frac{n+2-\alpha}{n}} - \frac{1}{\rho^{n+2-\alpha}} \right) f(y,s)\, dy\, ds.
\end{aligned}$$

It follows therefore from (3.13) and (3.17) that

$$\iint_{E_\rho(x,t)} \Phi(x-y,t-s)^{\frac{n+2-\alpha}{n}} f(y,s)\, dy\, ds \le C\rho^\alpha Mf(x,t) \quad \text{for } (x,t) \in \mathbb{R}^n \times \mathbb{R} \tag{3.18}$$

where $C = C(n, \alpha)$ is a positive constant.

Let q be the conjugate Hölder exponent of p. Then

$$\frac{1}{q} = 1 - \frac{1}{p} < 1 - \frac{\alpha}{n+2} = \frac{n+2-\alpha}{n+2}$$

and thus $\frac{n+2-\alpha}{n} q > \frac{n+2}{n}$. Hence by (3.10), (3.11), (3.13), and Hölder's inequality we get

$$\begin{aligned}
&\iint_{(\mathbb{R}^n \times \mathbb{R}) \setminus E_\rho(x,t)} \Phi(x-y, t-s)^{\frac{n+2-\alpha}{n}} f(y,s)\, dy\, ds \\
&\qquad \le \|f\|_{L^p(\mathbb{R}^n \times \mathbb{R})} \left(\iint_{E_\infty(x,t) \setminus E_\rho(x,t)} \Phi(x-y, t-s)^{\frac{n+2-\alpha}{n} q}\, dy\, ds \right)^{1/q} \\
&\qquad \le C \left(\frac{1}{\rho} \right)^{\frac{n+2}{p} - \alpha} \|f\|_{L^p(\mathbb{R}^n \times \mathbb{R})} \qquad (3.19)
\end{aligned}$$

where $C = C(n, \alpha, p)$ is a positive constant.

Taking

$$\rho = \left(\frac{\|f\|_p}{Mf(x,t)} \right)^{p/(n+2)}$$

and adding (3.18) and (3.19) yields (3.16). □

The following theorem is is the heat ball analog of the strong Hardy-Littlewood inequality for the maximal function (3.17).

Theorem 3.3. *Let $f \in L^p(\mathbb{R}^n \times \mathbb{R})$ be a nonnegative function where $p \in (1, \infty]$ and $n \ge 1$. Then*

$$\|Mf\|_{L^p(\mathbb{R}^n \times \mathbb{R})} \le C \|f\|_{L^p(\mathbb{R}^n \times \mathbb{R})} \qquad (3.20)$$

where $C = C(n, p)$ is a positive constant and Mf is given by (3.17).

Proof. The theorem is trivially true if $p = \infty$. Hence we can assume $1 < p < \infty$. Let r_0 be as in Lemma 3.1. By (3.12) and (3.13) we have

$$\frac{|E_r(x,t)|}{|Q_{r_0 r}(x,t)|} = \frac{r^{n+2} |E_1(0,0)|}{(r_0 r)^{n+2} |Q_1(0,0)|} = C(n).$$

Thus by Lemma 3.1,

$$\begin{aligned}
Mf(x,t) &= \sup_{r>0} \frac{1}{|E_r(x,t)|} \iint_{E_r(x,t)} f(y,s)\, dy\, ds \\
&\le \sup_{r>0} \frac{1}{C(n) |Q_{r_0 r}(x,t)|} \iint_{Q_{r_0 r}(x,t)} f(y,s)\, dy\, ds \\
&= \sup_{r>0} \frac{1}{C(n) |Q_r(x,t)|} \iint_{Q_r(x,t)} f(y,s)\, dy\, ds \\
&= \frac{1}{C(n)} \widehat{M} f(x,t)
\end{aligned}$$

where

$$\widehat{M} f(x,t) = \sup_{r>0} \frac{1}{|Q_r(x,t)|} \iint_{Q_r(x,t)} f(y,s)\, dy\, ds. \qquad (3.21)$$

Hence to complete the proof, it suffices to prove (3.20) with Mf replaced with $\widehat{M}f$. To do that we need the following d-ball analog of the weak Hardy-Littlewood inequality for the maximal function (3.21). By a d-ball we mean a ball in the metric space $(\mathbb{R}^n \times \mathbb{R}, d)$.

Proposition 3.1. *Let $g \in L^1(\mathbb{R}^n \times \mathbb{R})$ be a nonnegative function where $n \geq 1$. Then*

$$|\{\widehat{M}g > \lambda\}| < \frac{5^{n+2}}{\lambda} \|g\|_{L^1(\mathbb{R}^n \times \mathbb{R})} \quad \textit{for all } \lambda > 0.$$

Proof. Let $\lambda > 0$ be fixed. For each $(x,t) \in \{\widehat{M}g > \lambda\}$ there exists, by the definition of $\widehat{M}g$, $r(x,t) > 0$ such that

$$\iint_{Q_{r(x,t)}(x,t)} g(y,s)\, dy\, ds > \lambda |Q_{r(x,t)}(x,t)|.$$

Since $g \in L^1(\mathbb{R}^n \times \mathbb{R})$, the radii $r(x,t)$ of the balls $Q_{r(x,t)}(x,t)$, $(x,t) \in \{\widehat{M}g > \lambda\}$, are bounded. Thus by the Vitali covering lemma we can find among these balls a sequence $\{Q_j\}$ of pairwise disjoint balls such that

$$\bigcup_{j=1}^{\infty} 5Q_j \supset \{\widehat{M}g > \lambda\}.$$

Hence

$$|\{\widehat{M}g > \lambda\}| \leq \sum_{j=1}^{\infty} |5Q_j| = \sum_{j=1}^{\infty} 5^{n+2}|Q_j| < \frac{5^{n+2}}{\lambda}\|g\|_{L^1}.$$

□

Returning to the proof of Theorem 3.3, for each $\lambda > 0$, we define $h_\lambda(x,t) = f(x,t)$ if $f(x,t) > \lambda/2$ and 0 otherwise. Since $f \in L^p(\mathbb{R}^n \times \mathbb{R})$, $h_\lambda \in L^1(\mathbb{R}^n \times \mathbb{R})$. Also, it is easy to check that

$$\{\widehat{M}f > \lambda\} \subset \{\widehat{M}h_\lambda > \lambda/2\}.$$

Thus, by Proposition 3.1,

$$\begin{aligned} |\{\widehat{M}f > \lambda\}| &\leq |\{\widehat{M}h_\lambda > \lambda/2\}| \\ &\leq \frac{5^{n+2}}{\lambda/2}\|h_\lambda\|_{L^1(\mathbb{R}^n \times \mathbb{R})} \\ &= \frac{2(5^{n+2})}{\lambda} \iint_{\{f > \lambda/2\}} f(y,s)\, dy\, ds. \end{aligned} \tag{3.22}$$

Hence, by Lemma 3.2 with $b = 0, a = p-1, \alpha = 1, m = n+1$, and $g = \widehat{M}f$ we have

$$\begin{aligned} \|\widehat{M}f\|_p^p &= p\int_0^\infty \lambda^{p-1}|\{\widehat{M}f > \lambda\}|\, d\lambda \\ &\leq 2p5^{n+2}\int_0^\infty \lambda^{p-2}\left(\iint_{\{f > \lambda/2\}} f(y,s)\, dy\, ds\right) d\lambda \\ &= C(n,p)\|f\|_p^p \end{aligned}$$

where the last equation follows from Lemma 3.2 with $b = 1$, $a = p-2$, $\alpha = 2$, $m = n+1$, and $g = f$. □

The Sobolev inequality for heat potentials is given in the following theorem.

Theorem 3.4. *Suppose* $0 < \alpha < n+2$ *and* $1 < p < \frac{n+2}{\alpha}$ *are constants and* $f : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}$ *is a nonnegative measurable function. Let*

$$q = \frac{(n+2)p}{n+2-\alpha p}.$$

Then

$$\|J_\alpha * f\|_{L^q(\mathbb{R}^n\times\mathbb{R})} \le C\|f\|_{L^p(\mathbb{R}^n\times\mathbb{R})}$$

where $C = C(n,p,\alpha)$ *is a positive constant.*

Proof. By Theorems 3.2 and 3.3 we have

$$\begin{aligned}\|J_\alpha * f\|_q &\le C\|f\|_p^{\frac{\alpha p}{n+2}}\|(Mf)^{1-\frac{\alpha p}{n+2}}\|_q\\ &= C\|f\|_p^{\frac{\alpha p}{n+2}}\|Mf\|_p^{\frac{n+2-\alpha p}{n+2}}\\ &\le C\|f\|_p.\end{aligned}$$

□

We are now able to prove Theorem 3.1.

Proof of Theorem 3.1. Let $g = (J_\beta * f)^\sigma$. By Theorem 3.2, we have

$$\|J_\alpha * g\|_\infty \le C\|g\|_p^{\frac{\alpha p}{n+2}}\|g\|_\infty^{1-\frac{\alpha p}{n+2}} \quad \text{for } 1 \le p < \frac{n+2}{\alpha} \tag{3.23}$$

and

$$\|J_\beta * f\|_\infty \le C\|f\|_r^{\frac{\beta r}{n+2}}\|f\|_\infty^{1-\frac{\beta r}{n+2}} \tag{3.24}$$

because

$$1 \le r < \frac{(n+2)\sigma}{\alpha+\beta\sigma} = \frac{n+2}{\beta}\frac{\beta\sigma}{\alpha+\beta\sigma} < \frac{n+2}{\beta}.$$

Estimate (3.24) implies

$$\|g\|_\infty = \|J_\beta * f\|_\infty^\sigma \le C\|f\|_r^{\frac{\sigma\beta r}{n+2}}\|f\|_\infty^{\sigma-\frac{\sigma\beta r}{n+2}}. \tag{3.25}$$

It follows from (3.3) that there exist $s \in (r, (n+2)/\beta)$ and $p \in (1, (n+2)/\alpha)$ such that

$$p\sigma = \frac{(n+2)s}{n+2-\beta s}. \tag{3.26}$$

By Theorem 3.4 we have

$$\|g\|_p = \|J_\beta * f\|_{p\sigma}^\sigma \le C\|f\|_s^\sigma. \tag{3.27}$$

We now use (3.27) and (3.25) in (3.23) to obtain

$$\|J_\alpha * ((J_\beta * f)^\sigma)\|_\infty = \|J_\alpha * g\|_\infty \le C\|f\|_s^{\frac{\alpha p\sigma}{n+2}}\|f\|_r^{\frac{\sigma\beta r}{n+2}(1-\frac{\alpha p}{n+2})}\|f\|_\infty^{(\sigma-\frac{\sigma\beta r}{n+2})(1-\frac{\alpha p}{n+2})}. \tag{3.28}$$

Finally, using the estimate

$$\|f\|_s \le \|f\|_r^{\frac{r}{s}}\|f\|_\infty^{\frac{s-r}{s}}$$

in (3.28) gives

$$\begin{aligned}\|J_\alpha * ((J_\beta * f)^\sigma)\|_\infty &\le C\|f\|_r^{\frac{\alpha p\sigma r}{(n+2)s}+\frac{\sigma\beta r}{n+2}(1-\frac{\alpha p}{n+2})}\|f\|_\infty^{\frac{\alpha p\sigma}{n+2}\frac{s-r}{s}+(\sigma-\frac{\sigma\beta r}{n+2})(1-\frac{\alpha p}{n+2})} \\ &= C\|f\|_r^{\frac{(\alpha+\beta\sigma)r}{n+2}}\|f\|_\infty^{\frac{\sigma(n+2-\beta r)-\alpha r}{n+2}}\end{aligned}$$

by (3.26). □

Let $\Omega = \mathbb{R}^n \times (a,b)$ where $n \ge 1$ and $a < b$. The following theorem gives estimates for the heat potential

$$(V_\alpha f)(x,t) = \iint_\Omega \Phi(x-y,t-s)^{\frac{n+2-\alpha}{n}} f(y,s)\,dy\,ds,$$

where Φ is given by (1.4) and $\alpha \in (0, n+2)$.

Theorem 3.5. *Let $p, q \in [1,\infty]$, α, and δ satisfy*

$$0 \le \delta = \frac{1}{p} - \frac{1}{q} < \frac{\alpha}{n+2} < 1. \tag{3.29}$$

Then V_α maps $L^p(\Omega)$ continuously into $L^q(\Omega)$ and for $f \in L^p(\Omega)$ we have

$$\|V_\alpha f\|_{L^q(\Omega)} \le M\|f\|_{L^p(\Omega)}, \tag{3.30}$$

where

$$M = C(b-a)^{(\alpha-(n+2)\delta)/2} \quad \textit{for some constant } C = C(n,\alpha,\delta) > 0. \tag{3.31}$$

Theorem 3.5 is weaker than Theorem 3.4 in that the second inequality in (3.29) cannot be replaced with equality. However it is stronger in that the cases $p = 1$ and $q = \infty$ are allowed. These cases will be needed in Section 5 to prove Theorem 2.2.

Proof. This proof is a modification of the proof of Lemma 7.12 in [5] dealing with Riesz potentials. Let $\beta = \frac{n+2}{n}(1 - \frac{\alpha}{n+2})$ and $r = \frac{1}{1-\delta}$. Then by (3.29)

$$1 - \frac{n(\beta r - 1)}{2} = \frac{n+2}{2}\frac{\frac{\alpha}{n+2} - \delta}{1-\delta} > 0$$

and for $s < t$ we have

$$\begin{aligned}\int_{\mathbb{R}^n} \Phi(x-y,t-s)^{\beta r}\,dy &= \int_{\mathbb{R}^n} \Phi(x-y,t-s)^{\beta r}\,dx \\ &= \frac{1}{(4\pi)^{(\beta r-1)n/2}(\beta r)^{n/2}(t-s)^{(\beta r-1)n/2}}.\end{aligned}$$

Hence, letting $X = (x,t)$, $Y = (y,s)$, and $h = \Phi^\beta$ we have

$$\|h(X - \cdot)\|_{L^r(\Omega)} \le M \qquad \text{for all } X \in \Omega \tag{3.32}$$

and

$$\|h(\cdot - Y)\|_{L^r(\Omega)} \le M \qquad \text{for all } Y \in \Omega \tag{3.33}$$

where M is given by (3.31).

Since

$$\frac{r}{q} + r\left(1 - \frac{1}{p}\right) = r\left(1 + \frac{1}{q} - \frac{1}{p}\right) = r(1-\delta) = 1$$

and

$$\frac{p}{q}+p\delta=p\left(\frac{1}{q}+\delta\right)=1$$

we have

$$h(X-Y)|f(Y)|=h(X-Y)^{r/q}|f(Y)|^{p/q}h(X-Y)^{r(1-1/p)}|f(Y)|^{p\delta}.$$

Thus by Hölder's inequality and the fact that

$$\frac{1}{q}+\left(1-\frac{1}{p}\right)+\delta=1$$

we have

$$\begin{aligned}|V_\alpha f(X)| &\le \int_\Omega h(X-Y)|f(Y)|\,dY\\ &\le \left(\int_\Omega h(X-Y)^r|f(Y)|^p\,dY\right)^{1/q}\left(\int_\Omega h(X-Y)^r\,dY\right)^{1-1/p}\left(\int_\Omega |f(Y)|^p\,dY\right)^{\delta}.\end{aligned}$$

So by (3.32)

$$\|V_\alpha f\|_{L^q(\Omega)}\le M^{r(1-1/p)}\left(\int_\Omega |f(Y)|^p\,dY\right)^{\delta}J$$

where

$$\begin{aligned}J:&=\left(\int_\Omega\int_\Omega h(X-Y)^r|f(Y)|^p\,dY\,dX\right)^{1/q}\\ &=\left(\int_\Omega |f(Y)|^p\left(\int_\Omega h(X-Y)^r\,dX\right)\,dY\right)^{1/q}\\ &\le M^{r/q}\left(\int_\Omega |f(Y)|^p\,dY\right)^{1/q}\end{aligned}$$

by (3.33). Hence (3.30) follows from (3.29). □

4 Preliminary lemmas

In this section we provide some lemmas needed for the proofs of our results in Section 2.

Lemma 4.1. *Suppose u is a $C^{2,1}$ nonnegative solution of*

$$Hu\ge 0 \quad in \quad B_{\sqrt{4R}}(0)\times(0,4R)\subset\mathbb{R}^n\times\mathbb{R},\ n\ge 1, \tag{4.1}$$

where $Hu=u_t-\Delta u$ is the heat operator and R is a positive constant. Then

$$u, Hu\in L^1(B_{\sqrt{2R}}(0)\times(0,2R)) \tag{4.2}$$

and there exist a finite positive Borel measure μ on $B_{\sqrt{2R}}(0)$ and a bounded function $h\in C^{2,1}(B_{\sqrt{R}}(0)\times(-R,R))$ satisfying

$$Hh=0 \quad in \quad B_{\sqrt{R}}(0)\times(-R,R) \tag{4.3}$$

$$h=0 \quad in \quad B_{\sqrt{R}}(0)\times(-R,0] \tag{4.4}$$

such that

$$u = N + v + h \quad in \quad B_{\sqrt{R}}(0) \times (0, R) \tag{4.5}$$

where

$$N(x,t) := \int_0^{2R} \int_{|y|<\sqrt{2R}} \Phi(x-y, t-s) Hu(y,s)\, dy\, ds, \tag{4.6}$$

$$v(x,t) := \int_{|y|<\sqrt{2R}} \Phi(x-y, t)\, d\mu(y), \tag{4.7}$$

and Φ *is the heat kernel* (1.4)*.*

Proof. When $R = 1$, Lemma 4.1 was proved in [13]. The proof of Lemma 4.1 for R any positive constant is obtained by scaling the $R = 1$ case. ☐

Watson [14] provided another representation formula for distributional solutions of (4.1) in terms of integral potentials involving the Green function of the heat operator. See also Hirata [7].

Remark 4.1. Under the assumptions of Lemma 4.1 we have

$$(4\pi t)^{n/2} v(x,t) \le \int_{|y|<\sqrt{2R}} d\mu(y) < \infty \quad \text{for } (x,t) \in \mathbb{R}^n \times (0, \infty). \tag{4.8}$$

Thus by (4.5) we see that

$$u(x,t) \le C\left(\left(\frac{1}{\sqrt{t}}\right)^n + N(x,t)\right) \quad \text{for } (x,t) \in B_{\sqrt{R}}(0) \times (0, R).$$

To prove our results in Section 2, it will be convenient to use instead of the sets $P_r(x,t)$ and $E_r(x,t)$ the sets $\mathcal{P}_r(x,t)$ and $\mathcal{E}_r(x,t)$ defined by

$$\begin{matrix} \mathcal{P}_r(x,t) = P_{\sqrt{r}}(x,t) \\ \mathcal{E}_r(x,t) = E_{\sqrt{r}}(x,t) \end{matrix} \quad \text{for } (x,t) \in \mathbb{R}^n \times \mathbb{R} \quad \text{ and } r > 0. \tag{4.9}$$

It follows from (3.12) and (3.13) that

$$|\mathcal{P}_r(x,t)| = r^{\frac{n+2}{2}} |\mathcal{P}_1(0,0)| \tag{4.10}$$

$$|\mathcal{E}_r(x,t)| = r^{\frac{n+2}{2}} |\mathcal{E}_1(0,0)|. \tag{4.11}$$

Also, by Lemma 3.1,

$$\mathcal{E}_r(x,t) \subset \mathcal{P}_{r_0^2 r}(x,t) \tag{4.12}$$

where $r_0 = r_0(n)$ is as in Lemma 3.1.

Lemma 4.2. *Suppose* $(x_0, t_0) \in \mathbb{R}^n \times \mathbb{R}$ *and* $r > 0$*. If*

$$(x,t) \in \overline{\mathcal{P}_r(x_0,t_0)} \quad and \quad (y,s) \in (\mathbb{R}^n \times \mathbb{R}) \setminus \overline{\mathcal{P}_{2r}(x_0,t_0)}$$

then

$$\Phi(x-y, t-s) \le \frac{C(n)}{r^{n/2}}.$$

Proof. **Case I**. Suppose $t_0 - 2r \le s < t$. Then $|x-y| \ge (\sqrt{2}-1)\sqrt{r}$ and hence

$$\begin{aligned}\Phi(x-y,t-s) &\le \frac{e^{-\frac{(\sqrt{2}-1)^2 r}{4(t-s)}}}{(4\pi(t-s))^{n/2}} \le \sup_{\tau>0} \frac{e^{-\frac{(\sqrt{2}-1)^2 r}{4\tau}}}{(4\pi\tau)^{n/2}} \\ &= \sup_{\zeta>0} \frac{e^{-(\sqrt{2}-1)^2\zeta}}{(\pi r/\zeta)^{n/2}} = \frac{C(n)}{r^{n/2}}.\end{aligned}$$

Case II. Suppose $s < t_0 - 2r$. Then $t - s \ge r$ and hence

$$\Phi(x-y,t-s) \le \frac{1}{(4\pi r)^{n/2}} = \frac{C(n)}{r^{n/2}}.$$

Case III. Suppose $s \ge t$. Then $\Phi(x-y,t-s) = 0$. □

Lemma 4.3. *Suppose K is a compact subset of an open set $\Omega \subset \mathbb{R}^n$, $n \ge 1$, and $u(x,t)$ is a $C^{2,1}$ nonnegative solution of*

$$Hu \ge 0 \quad \text{in } \Omega \times (0,1). \tag{4.13}$$

Let $\{(x_j,t_j)\} \subset K \times (0,1)$ be a sequence such that

$$t_j \to 0 \quad \text{as } j \to \infty. \tag{4.14}$$

Then for some subsequence of $\{(x_j,t_j)\}$, which we denote again by $\{(x_j,t_j)\}$, we have

$$\mathcal{P}_{t_j}(x_j,t_j) \subset \Omega \times (0,1), \tag{4.15}$$

$$\iint_{\mathcal{P}_{t_j}(x_j,t_j)} Hu(x,t)\,dx\,dt \to 0 \quad \text{as } j \to \infty, \tag{4.16}$$

and, for all $a \ge 1$,

$$u(x,t) \le C\left[\left(\frac{1}{\sqrt{t_j}}\right)^n + \iint_{\mathcal{P}_{t_j/a}(x_j,t_j)} \Phi(x-y,t-s)Hu(y,s)\,dy\,ds\right] \quad \text{for } (x,t) \in \overline{\mathcal{P}_{t_j/2a}(x_j,t_j)} \tag{4.17}$$

where $C > 0$ does not depend on (x,t) or j (but may depend on a).

Proof. By taking a subsequence of $\{(x_j,t_j)\}$ we can assume there exists $x_0 \in K$ such that $x_j \to x_0$ as $j \to \infty$, and, for some $\varepsilon > 0$, $\mathcal{P}_{4\varepsilon}(x_0,4\varepsilon) \subset \Omega \times (0,1)$ and

$$\overline{\mathcal{P}_{t_j}(x_j,t_j)} \subset \mathcal{P}_\varepsilon(x_0,\varepsilon) \quad \text{for } j = 1,2,\ldots. \tag{4.18}$$

Thus (4.15) holds.

By (4.13), Lemma 4.1, and Remark 4.1, we have

$$\iint_{\mathcal{P}_{2\varepsilon}(x_0,2\varepsilon)} Hu(x,t)\,dx\,dt < \infty \tag{4.19}$$

and, for $(x,t) \in \mathcal{P}_\varepsilon(x_0,\varepsilon)$,

$$u(x,t) \le C\left[\left(\frac{1}{\sqrt{t}}\right)^n + \iint_{\mathcal{P}_{2\varepsilon}(x_0,2\varepsilon)} \Phi(x-y,t-s)Hu(y,s)\,dy\,ds\right] \tag{4.20}$$

where $C > 0$ does not depend on (x,t). However, for

$$(x,t) \in \overline{\mathcal{P}_{t_j/2a}(x_j,t_j)} \quad \text{and} \quad (y,s) \in \mathcal{P}_{2\varepsilon}(x_0,2\varepsilon)\backslash\overline{\mathcal{P}_{t_j/a}(x_j,t_j)}$$

we have by Lemma 4.2 that

$$\Phi(x-y,t-s) \le C(n)\left(\frac{a}{t_j}\right)^{n/2}$$

and thus by (4.19) we find that

$$\iint_{\mathcal{P}_{2\varepsilon}(x_0,2\varepsilon)\backslash\mathcal{P}_{t_j/a}(x_j,t_j)} \Phi(x-y,t-y)Hu(y,s)\,dy\,ds < \frac{C}{t_j^{n/2}} \qquad \text{for } (x,t) \in \overline{\mathcal{P}_{t_j/2a}(x_j,t_j)}.$$

Inequality (4.17) therefore follows from (4.20). Finally, (4.18) and (4.19) imply (4.16). $\square$

Lemma 4.4. *Suppose $\Omega_2 \subset\subset \Omega_1 \subset\subset \Omega_0$ are nonempty open subsets of $\mathbb{R}^n, n \ge 1$. Let $u(x,t)$ be a $C^{2,1}$ nonnegative solution of*

$$Hu \ge 0 \qquad \text{in } \Omega_0 \times (0,1)$$

satisfying

$$\max_{x\in\overline{\Omega}_1} Hu(x,t) = O\left(\left(\frac{1}{\sqrt{t}}\right)^{\gamma}\right) \qquad \text{as } t \to 0^+ \tag{4.21}$$

where γ is a real constant. Then

$$\max_{x\in\overline{\Omega}_2} u(x,t) = O\left(\left(\frac{1}{\sqrt{t}}\right)^{n}\right) + o\left(\left(\frac{1}{\sqrt{t}}\right)^{\gamma\frac{n}{n+2}}\right) \qquad \text{as } t \to 0^+. \tag{4.22}$$

If, in addition, $\gamma > n+2$ and $v(x,t)$ is a $C^{2,1}$ nonnegative solution of

$$0 \le Hv \le \left(u + \left(\frac{1}{\sqrt{t}}\right)^{n}\right)^{\sigma} \qquad \text{in } \Omega_0 \times (0,1) \tag{4.23}$$

where $\sigma > \frac{2}{n}$ then

$$\max_{x\in\overline{\Omega}_2} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}}\right)^{n}\right) + o\left(\left(\frac{1}{\sqrt{t}}\right)^{\gamma\frac{n\sigma-2}{n+2}}\right) \qquad \text{as } t \to 0^+. \tag{4.24}$$

Proof. For the proof of (4.22) we can assume $\gamma \ge n+2$ because increasing γ to $n+2$ weakens condition (4.21) and does not change (4.22).

Suppose for contradiction that (4.22) is false. Then there exists a sequence $\{(x_j,t_j)\} \subset \overline{\Omega}_2 \times (0,1)$ such that $t_j \to 0$ as $j \to \infty$ and either

$$\lim_{j\to\infty} \sqrt{t_j}^{\,n} u(x_j,t_j) = \infty \quad \text{if } n \ge \gamma\frac{n}{n+2} \tag{4.25}$$

or

$$\liminf_{j\to\infty} \sqrt{t_j}^{\,\gamma\frac{n}{n+2}} u(x_j,t_j) > 0 \quad \text{if } n < \gamma\frac{n}{n+2}. \tag{4.26}$$

By taking a subsequence, we have by Lemma 4.3 with $\Omega = \Omega_1$, $K = \overline{\Omega}_2$, and $a = 2$ applied to the function u that the sequence $\{(x_j,t_j)\}$ satisfies

$$\mathcal{P}_{t_j}(x_j,t_j) \subset \Omega_1 \times (0,1) \tag{4.27}$$

and the function u satisfies (4.16) and (4.17).

By (4.21) and (4.27) we have

$$Hu(x,t) \le \frac{A}{\sqrt{t_j}^{\gamma}} \quad \text{for } (x,t) \in \mathcal{P}_{t_j/2}(x_j,t_j) \tag{4.28}$$

where A is a positive constant which does not depend on (x,t) or j.

Define $r_j \ge 0$ by

$$\iint_{\mathcal{E}_{r_j}(x_j,t_j)} \frac{A}{\sqrt{t_j}^{\gamma}}\, dx\, dt = \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)} Hu(x,t)\, dx\, dt \to 0 \quad \text{as } j \to \infty \tag{4.29}$$

by (4.16). Then by (4.11) we have

$$r_j = o\left(t_j^{\frac{\gamma}{n+2}}\right) << t_j \quad \text{as } j \to \infty \tag{4.30}$$

because $\gamma \ge n+2$. Hence by (4.12),

$$\mathcal{E}_{r_j}(x_j,t_j) \subset \mathcal{P}_{t_j/2}(x_j,t_j) \quad \text{for large } j.$$

Thus by (4.9), (4.28) and (4.29) we have for large j that

$$\begin{aligned} &\iint_{\mathcal{E}_{r_j}(x_j,t_j)} \Phi(x_j - y, t_j - s)\left(\frac{A}{\sqrt{t_j}^{\gamma}} - Hu(y,s)\right) dy\, ds \\ &\qquad \ge \frac{1}{r_j^{n/2}} \iint_{\mathcal{E}_{r_j}(x_j,t_j)} \left(\frac{A}{\sqrt{t_j}^{\gamma}} - Hu(y,s)\right) dy\, ds \\ &\qquad = \frac{1}{r_j^{n/2}} \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)\setminus\mathcal{E}_{r_j}(x_j,t_j)} Hu(y,s)\, dy\, ds \\ &\qquad \ge \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)\setminus\mathcal{E}_{r_j}(x_j,t_j)} \Phi(x_j - y, t_j - s) Hu(y,s)\, dy\, ds. \end{aligned}$$

So for large j we have

$$\begin{aligned} \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)} \Phi(x_j - y, t_j - s) Hu(y,s)\, dy\, ds &\le \frac{A}{\sqrt{t_j}^{\gamma}} \iint_{\mathcal{E}_{r_j}(x_j,t_j)} \Phi(x_j - y, t_j - s)\, dy\, ds \\ &\le \frac{A r_0^2 r_j}{\sqrt{t_j}^{\gamma}} \end{aligned}$$

by (4.12) and the fact that $\int_{\mathbb{R}^n} \Phi(x_j - y, t_j - s)\, dy\, ds = 1$ for $s < t_j$. Hence by (4.17) and (4.30) we find that

$$\begin{aligned} u(x_j,t_j) &\le C\left[\left(\frac{1}{\sqrt{t_j}}\right)^n + \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)} \Phi(x_j - y, t_j - s) Hu(y,s)\, dy\, ds\right] \\ &\le C\left[\left(\frac{1}{\sqrt{t_j}}\right)^n + \frac{A r_0^2 r_j}{\sqrt{t_j}^{\gamma}}\right] \\ &= C\left[\left(\frac{1}{\sqrt{t_j}}\right)^n + o\left(\left(\frac{1}{\sqrt{t_j}}\right)^{\gamma\frac{n}{n+2}}\right)\right] \quad \text{as } j \to 0 \end{aligned}$$

which contradicts (4.25), (4.26) and thereby proves (4.22).

Suppose for contradiction that (4.24) is false. Then there exists a sequence $\{(x_j, t_j)\} \subset \overline{\Omega}_2 \times (0,1)$ such that $t_j \to 0$ as $j \to \infty$ and either

$$\lim_{j\to\infty} \sqrt{t_j}^{\,n} v(x_j, t_j) = \infty \qquad \text{if } n \geq \gamma \frac{n\sigma - 2}{n+2} \tag{4.31}$$

or

$$\liminf_{j\to\infty} \sqrt{t_j}^{\,\gamma \frac{n\sigma-2}{n+2}} v(x_j, t_j) > 0 \qquad \text{if } n < \gamma \frac{n\sigma - 2}{n+2}. \tag{4.32}$$

By taking a subsequence, we have by Lemma 4.3 with $\Omega = \Omega_1$, $K = \overline{\Omega}_2$, and $a = 2$ applied to the function u that the sequence $\{(x_j, t_j)\}$ satisfies (4.27) and the function u satisfies (4.16) and (4.17). Thus for $(x,t) \in \overline{\mathcal{P}_{t_j/4}(x_j, t_j)}$ we have by (4.23) that

$$Hv(x,t) \leq \left(u(x,t) + \left(\frac{1}{\sqrt{t}}\right)^n \right)^\sigma \leq C \left[\left(\frac{1}{\sqrt{t_j}}\right)^{n\sigma} + \left((N_{\mathcal{P}_{t_j/2}(x_j,t_j)}(Hu))(x,t) \right)^\sigma \right]$$

where

$$(N_D f)(x,t) := \iint_D \Phi(x-y, t-s) f(y,s)\, dy\, ds.$$

Hence applying Lemma 4.3 to v with $\Omega = \Omega_1$, $K = \overline{\Omega}_2$, and $a = 4$ we get

$$\begin{aligned} v(x_j, t_j) &\leq C \left[\left(\frac{1}{\sqrt{t_j}}\right)^n + \iint_{\mathcal{P}_{t_j/4}(x_j,t_j)} \Phi(x_j - y, t_j - s) Hv(y,s)\, dy\, ds \right] \\ &\leq C \left[\left(\frac{1}{\sqrt{t_j}}\right)^n + \left(\frac{1}{\sqrt{t_j}}\right)^{n\sigma-2} + (K_j(Hu))(x_j, t_j) \right] \end{aligned} \tag{4.33}$$

where

$$K_j f = N_{\mathcal{P}_{t_j/2}(x_j,t_j)} \left((N_{\mathcal{P}_{t_j/2}(x_j,t_j)} f)^\sigma \right).$$

Since $\sigma > \frac{2}{n}$ we find using (4.16) and (4.21) in Theorem 3.1 (with $\alpha = \beta = 2$ and $r = 1$) that

$$(K_j(Hu))(x_j, t_j) = o\left(\left(\frac{1}{\sqrt{t_j}}\right)^{\gamma \frac{n\sigma-2}{n+2}} \right) \qquad \text{as } j \to \infty.$$

Thus (4.33) contradicts (4.31, 4.32). This completes the proof of (4.24). □

Lemma 4.5. *Suppose u and v are $C^{2,1}$ nonnegative solutions of the system*

$$\begin{aligned} 0 &\leq Hu \\ 0 &\leq Hv \leq \left(u + \left(\frac{1}{\sqrt{t}}\right)^n \right)^\sigma \qquad \text{in } \Omega \times (0,1) \end{aligned} \tag{4.34}$$

where Ω is a open subset of $\mathbb{R}^n$, $n \geq 1$. Let K be a compact subset of Ω.

(i) If $\sigma < 2/n$ then

$$\max_{x\in K} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}}\right)^n \right) \qquad \text{as } t \to 0^+. \tag{4.35}$$

(ii) If

$$\lambda > \frac{n+2}{n} \qquad \text{and} \qquad \sigma < \frac{2}{n} + \frac{n+2}{n\lambda} \tag{4.36}$$

and

$$Hu \le \left(v + \left(\frac{1}{\sqrt{t}} \right)^n \right)^\lambda \qquad \text{in } \Omega \times (0,1) \tag{4.37}$$

then for some $\gamma > n+2$ we have

$$\max_{x \in K} Hu(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^\gamma \right) \qquad \text{as } t \to 0^+. \tag{4.38}$$

Proof. We can assume for the proof of (i) (resp. (ii)) that

$$0 < \sigma < \frac{2}{n} \tag{4.39}$$

$$\left(\text{resp. } \frac{2}{n} < \sigma < \frac{2}{n} + \frac{n+2}{n\lambda} \right) \tag{4.40}$$

because increasing σ weakens the condition $(4.34)_2$ on v but does not change the estimates (4.35) or (4.38).

Suppose for contradiction that (i) (resp. (ii)) is false. Then there exists a sequence $\{(x_j, t_j)\} \subset K \times (0,1)$ such that $t_j \to 0$ as $j \to \infty$ and

$$\sqrt{t_j}^{\,n} v(x_j, t_j) \to \infty \qquad \text{as } j \to \infty \tag{4.41}$$

$$(\text{resp. } \sqrt{t_j}^{\,\gamma} Hu(x_j, t_j) \to \infty \qquad \text{as } j \to \infty \tag{4.42}$$

for all $\gamma > n+2$). To obtain a single sequence $\{(x_j, t_j)\}$ such that (4.42) holds for all $\gamma > n+2$, one uses a standard diagonalization argument.

By taking a subsequence we have by Lemma 4.3 that $\mathcal{P}_{t_j}(x_j, t_j) \subset \Omega \times (0,1)$,

$$\iint_{\mathcal{P}_{t_j/2}(x_j,t_j)} Hu(y,s)\, dy\, ds \to 0 \quad \text{and} \quad \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)} Hv(y,s)\, dy\, ds \to 0 \quad \text{as } j \to \infty, \tag{4.43}$$

and for $(x,t) \in \overline{\mathcal{P}_{t_{j/4}}(x_j, t_j)}$ we have

$$u(x,t) \le C \left[\left(\frac{1}{\sqrt{t_j}} \right)^n + \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)} \Phi(x-y, t-s) Hu(y,s)\, dy\, ds \right] \tag{4.44}$$

$$v(x,t) \le C \left[\left(\frac{1}{\sqrt{t_j}} \right)^n + \iint_{\mathcal{P}_{t_j/2}(x_j,t_j)} \Phi(x-y, t-s) Hv(y,s)\, dy\, ds \right] \tag{4.45}$$

where $C > 0$ does not depend on (x,t) or j.

Define $f_j, g_j : \mathcal{P}_2(0,2) \to [0,\infty)$ by

$$f_j(\eta, \zeta) = r_j^{\frac{n+2}{2}} Hu(x_j + \sqrt{r_j}\eta, t_j + r_j\zeta)$$

$$g_j(\eta, \zeta) = r_j^{\frac{n+2}{2}} Hv(x_j + \sqrt{r_j}\eta, t_j + r_j\zeta)$$

where $r_j = t_j/4$. Making the change of variables

$$x = x_j + \sqrt{r_j}\xi, \quad t = t_j + r_j\tau$$

$$y = x_j + \sqrt{r_j}\eta, \quad s = t_j + r_j\zeta$$

in (1.4), (4.43), (4.44), and (4.45) we get

$$\Phi(x-y, t-s) = r_j^{-n/2}\Phi(\xi-\eta, \tau-\zeta),$$

$$\iint_{\mathcal{P}_2(0,0)} f_j(\eta,\zeta)\, d\eta\, d\zeta \to 0 \quad \text{and} \quad \iint_{\mathcal{P}_2(0,0)} g_j(\eta,\zeta)\, d\eta\, d\zeta \to 0 \quad \text{as } j \to \infty, \tag{4.46}$$

and

$$u(x_j + \sqrt{r_j}\xi, t_j + r_j\tau) \le \frac{C}{r_j^{n/2}}\left[1 + (N_2 f_j)(\xi,\tau)\right] \quad \text{for } (\xi,\tau) \in \mathcal{P}_1(0,0) \tag{4.47}$$

$$v(x_j + \sqrt{r_j}\xi, t_j + r_j\tau) \le \frac{C}{r_j^{n/2}}\left[1 + N_2 g_j(\xi,\tau)\right] \quad \text{for } (\xi,\tau) \in \mathcal{P}_1(0,0) \tag{4.48}$$

where

$$(N_R f)(\xi,\tau) := \iint_{\mathcal{P}_R(0,0)} \Phi(\xi-\eta, \tau-\zeta) f(\eta,\zeta)\, d\eta\, d\zeta.$$

We now prove part (i). Define $\varepsilon \in (0,1)$ and $\gamma > 0$ by $\sigma = \frac{2}{n}(1-\varepsilon)^2$ and $\gamma = \frac{n+2}{n}(1-\varepsilon)$. It follows from (4.46) and Theorem 3.5 with $p = 1$ and $\alpha = 2$ that $N_2 f_j \to 0$ in $L^\gamma(\mathcal{P}_2(0,0))$ and hence

$$(N_2 f_j)^\sigma \to 0 \quad \text{in } L^{\frac{n+2}{2(1-\varepsilon)}}(\mathcal{P}_2(0,0)).$$

Thus by Hölder's inequality

$$\iint_{\mathcal{P}_1(0,0)} \Phi^*(N_2 f_j)^\sigma\, d\eta\, d\zeta \le \|\Phi^*\|_{\frac{n+2}{n+2\varepsilon}} \|(N_2 f_j)^\sigma\|_{\frac{n+2}{2(1-\varepsilon)}} \to 0 \quad \text{as } j \to \infty \tag{4.49}$$

where $\Phi^*(\eta,\zeta) = \Phi(\eta,-\zeta)$. By (4.48) and (4.46) we have

$$\begin{aligned} v(x_j,t_j) &\le \frac{C}{\sqrt{t_j}^n}\left(1 + \iint_{\mathcal{P}_2(0,0)} \Phi^* g_j\, d\xi\, d\tau\right) \\ &\le \frac{C}{\sqrt{t_j}^n}\left(1 + \iint_{\mathcal{P}_1(0,0)} \Phi^* g_j\, d\xi\, d\tau\right) \end{aligned} \tag{4.50}$$

and for $(\xi,\tau) \in \mathcal{P}_1(0,0)$ it follows from $(4.34)_2$ and (4.47) that

$$\begin{aligned} g_j(\xi,\tau) &= r_j^{\frac{n+2}{2}}(Hv)(x,t) \\ &\le r_j^{\frac{n+2}{2}}\left(u(x,t) + \left(\frac{1}{\sqrt{t_j}}\right)^n\right)^\sigma \\ &\le C(\sqrt{t_j})^{n+2-n\sigma}(1 + N_2 f_j(\xi,\tau))^\sigma. \end{aligned} \tag{4.51}$$

Substituting (4.51) in (4.50) and using (4.49) we get $v(x_j,t_j) \le C\frac{1}{\sqrt{t_j}^n}$ which contradicts (4.41) and thereby completes the proof of part (i).

We next prove part (ii). It follows from (4.46), (4.47), (4.48) and Lemma 4.2 that for $R \in (0, \frac{1}{2}]$ we have

$$u(x_j + \sqrt{r_j}\eta, t_j + r_j\zeta) \le \frac{C}{r_j^{n/2}}\left[\frac{1}{R^{n/2}} + (N_{4R}f_j)(\eta,\zeta)\right] \qquad \text{for } (\eta,\zeta) \in \mathcal{P}_{2R}(0,0)$$

and

$$v(x_j + \sqrt{r_j}\xi, t_j + r_j\tau) \le \frac{C}{r_j^{n/2}}\left[\frac{1}{R^{n/2}} + (N_{2R}g_j)(\xi,\tau)\right] \qquad \text{for } (\xi,\tau) \in \mathcal{P}_{R}(0,0)$$

where C is independent of (ξ,τ), (η,ζ), j, and R. It therefore follows from $(4.34)_2$ and (4.37) that for $R \in (0, \frac{1}{2}]$ we have

$$\begin{aligned} r_j^{-\frac{n+2}{2}} f_j(\xi,\tau) &= (Hu)(x_j + \sqrt{r_j}\xi, t_j + r_j\tau) \\ &\le C\left(\frac{1}{r_j^{n/2}}\left[\frac{1}{R^{n/2}} + (N_{2R}g_j)(\xi,\tau)\right]\right)^{\lambda} \\ &\le C r_j^{-n\lambda/2}\left[\frac{1}{R^{n\lambda/2}} + (N_{2R}g_j)(\xi,\tau)^{\lambda}\right] \qquad \text{for } (\xi,\tau) \in \mathcal{P}_R(0,0) \end{aligned} \tag{4.52}$$

and

$$\begin{aligned} r_j^{-\frac{n+2}{2}} g_j(\eta,\zeta) &= (Hv)(x_j + \sqrt{r_j}\eta, t_j + r_j\zeta) \\ &\le C\left(\frac{1}{r_j^{n/2}}\left[\frac{1}{R^{n/2}} + (N_{4R}f_j)(\eta,\zeta)\right]\right)^{\sigma} \\ &\le C r_j^{-n\sigma/2}\left[\frac{1}{R^{n\sigma/2}} + (N_{4R}f_j)(\eta,\zeta)^{\sigma}\right] \qquad \text{for } (\eta,\zeta) \in \mathcal{P}_{2R}(0,0). \end{aligned}$$

Thus for $(\xi,\tau) \in \mathbb{R}^n \times \mathbb{R}$ we have

$$\begin{aligned} ((N_{2R}g_j)(\xi,\tau))^{\lambda} &\le C\left(r_j^{\frac{n+2}{2}-\frac{n\sigma}{2}} N_{2R}\left[\frac{1}{R^{n\sigma/2}} + (N_{4R}f_j)^{\sigma}\right](\xi,\tau)\right)^{\lambda} \\ &\le C r_j^{\frac{(n+2-n\sigma)\lambda}{2}}\left[R^{(1-n\sigma/2)\lambda} + ((M_{4R}f_j)(\xi,\tau))^{\lambda}\right] \end{aligned}$$

where $M_R f := N_R((N_R f)^{\sigma})$. Hence by (4.52) there exists a positive constant a which depends only on n, λ, and σ such that for $R \in (0, \frac{1}{2}]$ we have

$$f_j(\xi,\tau) \le C\frac{1}{(Rr_j)^a}\left(1 + ((M_{4R}f_j)(\xi,\tau))^{\lambda}\right) \qquad \text{for } (\xi,\tau) \in \mathcal{P}_R(0,0). \tag{4.53}$$

By (4.36) there exists $\varepsilon = \varepsilon(n,\lambda,\sigma) \in (0,1)$ such that

$$\sigma < \frac{n+2}{n+\varepsilon} \quad \text{and } \sigma < \frac{2-\varepsilon}{n+\varepsilon} + \frac{n+2}{n+\varepsilon}\frac{1}{\lambda}. \tag{4.54}$$

To show that (4.42) cannot hold for all $\gamma > n+2$ and thereby complete the proof of (ii), it suffices by the definition of r_j and f_j to show for some $\gamma > 0$ that the sequence

$$\{r_j^{\gamma} f_j(0,0)\} \text{ is bounded.} \tag{4.55}$$

To prove (4.55) we need the following result.

Lemma 4.6. *Suppose the sequence*

$$\{r_j^\alpha f_j\} \text{ is bounded in } L^p(\mathcal{P}_{4R}(0,0)) \tag{4.56}$$

for some constants $\alpha \geq 0$, $p \in [1,\infty)$ and $R \in (0,\frac{1}{2}]$. Let $\beta = \alpha\lambda\sigma + a$ where a is as in (4.53). Then either the sequence

$$\{r_j^\beta f_j\} \text{ is bounded in } L^\infty(\mathcal{P}_R(0,0)) \tag{4.57}$$

or there exists a positive constant $C_0 = C_0(n,\lambda,\sigma)$ such that the sequence

$$\{r_j^\beta f_j\} \text{ is bounded in } L^q(\mathcal{P}_R(0,0)) \tag{4.58}$$

for some $q \in (p,\infty)$ satisfying

$$\frac{1}{p} - \frac{1}{q} > C_0. \tag{4.59}$$

Proof. It follows from (4.53) that

$$r_j^\beta f_j(\xi,\tau) \leq \frac{C}{R^a}\left(1 + (M_{4R}(r_j^\alpha f_j))(\xi,\tau))^\lambda\right) \quad \text{for } (\xi,\tau) \in \mathcal{P}_R(0,0). \tag{4.60}$$

We can assume

$$p \leq \frac{n+2}{2} \tag{4.61}$$

for otherwise from Theorem 3.5 and (4.56) we find that the sequence $\{N_{4R}(r_j^\alpha f_j)\}$ is bounded in $L^\infty(\mathcal{P}_{4R}(0,0))$ and hence by (4.60) we see that (4.57) holds.

Define p_2 by

$$\frac{1}{p} - \frac{1}{p_2} = \frac{2-\varepsilon}{n+2} \tag{4.62}$$

where $\varepsilon = \varepsilon(n,\lambda,\sigma)$ is as in (4.54). By (4.61), $p_2 \in (p,\infty)$ and by Theorem 3.5 we have

$$\|(N_{4R}f_j)^\sigma\|_{p_2/\sigma} = \|N_{4R}f_j\|_{p_2}^\sigma \leq C\|f_j\|_p^\sigma \tag{4.63}$$

where $\|\cdot\|_p := \|\cdot\|_{L^p(\mathcal{P}_{4R}(0,0))}$. Since, by (4.54),

$$\frac{1}{p_2} = \frac{1}{p} - \frac{2-\varepsilon}{n+2} \leq 1 - \frac{2-\varepsilon}{n+2} = \frac{n+\varepsilon}{n+2} < \frac{1}{\sigma}$$

we have

$$\frac{p_2}{\sigma} > 1. \tag{4.64}$$

We can assume

$$p_2/\sigma \leq (n+2)/2 \tag{4.65}$$

for otherwise by Theorem 3.5 and (4.63) we have

$$\|M_{4R}(r_j^\alpha f_j)\|_\infty \leq C\|(N_{4R}(r_j^\alpha f_j))^\sigma\|_{p_2/\sigma} \leq C\|r_j^\alpha f_j\|_p^\sigma$$

which is bounded by (4.56). Hence by (4.60) we see that (4.57) holds.

Define p_3 and q by

$$\frac{\sigma}{p_2} - \frac{1}{p_3} = \frac{2-\varepsilon}{n+2} \quad \text{and} \quad q = \frac{p_3}{\lambda}. \tag{4.66}$$

By (4.64) and (4.65), $p_3 \in (1,\infty)$ and by Theorem 3.5

$$\begin{aligned}\| (M_{4R} f_j)^\lambda \|_q &= \| M_{4R} f_j \|_{p_3}^\lambda \\ &\le C \| (N_{4R} f_j)^\sigma \|_{p_2/\sigma}^\lambda \le C \| f_j \|_p^{\lambda\sigma}\end{aligned}$$

by (4.63). It follows therefore from (4.60) that

$$\| r_j^\beta f_j \|_{L^q(\mathcal{P}_R(0,0))} \le \frac{C}{R^a} \left(1 + \| r_j^\alpha f_j \|_p^{\lambda\sigma} \right)$$

which is a bounded sequence by (4.56). It remains to prove that q satisfies (4.59) for some positive constant $C_0 = C_0(n,\lambda,\sigma)$.

By (4.62) and (4.66) we have

$$\begin{aligned}\frac{1}{p} - \frac{1}{q} = \frac{1}{p} - \frac{\lambda}{p_3} &= \frac{1}{p} + \frac{(2-\varepsilon)\lambda}{n+2} - \frac{\lambda\sigma}{p_2} \\ &= \frac{1}{p} + \frac{(2-\varepsilon)\lambda}{n+2} + \frac{(2-\varepsilon)\lambda\sigma}{n+2} - \frac{\lambda\sigma}{p} \\ &= -\frac{\lambda\sigma - 1}{p} + \frac{(2-\varepsilon)\lambda\sigma + (2-\varepsilon)\lambda}{n+2}.\end{aligned} \tag{4.67}$$

Case I. Suppose $\lambda\sigma \le 1$. Then by (4.67), (4.36), and (4.40) we get

$$\frac{1}{p} - \frac{1}{q} \ge \frac{(2-\varepsilon)\lambda\sigma + (2-\varepsilon)\lambda}{n+2} \ge C_1(n) > 0.$$

Case II. Suppose $\lambda\sigma > 1$. Then, by (4.67),

$$\begin{aligned}\frac{1}{p} - \frac{1}{q} &\ge 1 - \sigma\lambda + \frac{(2-\varepsilon)\lambda\sigma + (2-\varepsilon)\lambda}{n+2} \\ &= \frac{1}{n+2}[n + 2 + (2-\varepsilon)\lambda - \lambda\sigma(n + 2 - (2-\varepsilon))] \\ &= \frac{(n+\varepsilon)\lambda}{n+2}\left[\frac{2-\varepsilon}{n+\varepsilon} + \frac{n+2}{n+\varepsilon}\frac{1}{\lambda} - \sigma\right] \\ &= C_2(n,\lambda,\sigma) > 0\end{aligned}$$

by (4.54).

Thus (4.59) holds with $C_0 = \min(C_1, C_2)$. This completes the proof of Lemma 4.6. □

We return now to the proof of Lemma 4.5(ii). By (4.46), the sequence $\{f_j\}$ is bounded in $L^1(\mathcal{P}_2(0,0))$. Starting with this fact and iterating Lemma 4.6 a finite number of times (m times is enough if $m > 1/C_0$) we see that there exists $R_0 \in (0, \frac{1}{2})$ and $\gamma > n$ such that sequence $\{r_j^\gamma f_j\}$ is bounded in $L^\infty(\mathcal{P}_{R_0}(0,0))$. In particular (4.55) holds. This completes the proof of Lemma 4.5(ii). □

5 Proofs

In this section we prove the results in Section 2.

Proof of Theorem 2.1. Since increasing σ and/or λ weakens the conditions (2.1) on u and v, we can assume $\sigma = \lambda = \frac{n+2}{n}$. Let $w = u + v$. Then it follows from (2.1) that in $\Omega \times (0,1)$ we have

$$\begin{aligned} 0 \le Hw = Hu + Hv &\le \left(v + \left(\frac{1}{\sqrt{t}} \right)^n \right)^{\frac{n+2}{n}} + \left(u + \left(\frac{1}{\sqrt{t}} \right)^n \right)^{\frac{n+2}{n}} \\ &\le C \left(w + \left(\frac{1}{\sqrt{t}} \right)^n \right)^{\frac{n+2}{n}} \end{aligned}$$

for some positive constant C. Thus by [13, Theorem 1.1] for each compact subset K of Ω we have

$$\max_{x \in K} (u(x,t) + v(x,t)) = \max_{x \in K} w(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^n \right) \qquad \text{as } t \to 0^+$$

which proves (2.3) and (2.4). □

Proof of Theorem 2.2. Since increasing σ weakens the conditions on u and v in (2.1) but does not change the estimates (2.6) and (2.7), we can, instead of (2.5), assume

$$\lambda > \frac{n+2}{n} \quad \text{and} \quad \frac{2}{n} < \sigma < \frac{2}{n} + \frac{n+2}{n\lambda}. \tag{5.1}$$

Let $\{\Omega_i\}$ be a sequence of bounded open subsets of $\mathbb{R}^n$ such that

$$\overline{\Omega}_i \subset \Omega \quad \text{and } K \subset \overline{\Omega}_{i+1} \subset \Omega_i \quad \text{for } i = 1, 2, \ldots.$$

By Lemma 4.5(ii), for some $\gamma > n+2$ we have

$$\max_{x \in \overline{\Omega}_1} Hu(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^\gamma \right) \qquad \text{as } t \to 0^+.$$

Hence by Lemma 4.4

$$\max_{x \in \overline{\Omega}_2} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^p \right) \qquad \text{as } t \to 0^+ \tag{5.2}$$

for some $p > n$. Thus by (2.1),

$$\max_{x \in \overline{\Omega}_2} Hu(x,t) \le O\left(\left(\frac{1}{\sqrt{t}} \right)^{p\lambda} \right) \qquad \text{as } t \to 0^+.$$

Thus by Lemma 4.4 we get

$$\max_{x \in \overline{\Omega}_3} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^n \right) + o\left(\left(\frac{1}{\sqrt{t}} \right)^{p\lambda \frac{n\sigma - 2}{n+2}} \right) \qquad \text{as } t \to 0^+. \tag{5.3}$$

By (5.1), $\lambda \frac{n\sigma - 2}{n+2} < 1$. Thus iterating a finite number of times the procedure of going from (5.2) to (5.3) we obtain for some positive integer k that

$$\max_{x \in \overline{\Omega}_k} v(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^n \right) \qquad \text{as } t \to 0^+ \tag{5.4}$$

which clearly implies (2.7). It follows from (5.4) and $(2.1)_1$ that

$$\max_{x \in \overline{\Omega}_k} Hu(x,t) = O\left(\left(\frac{1}{\sqrt{t}} \right)^{n\lambda} \right) \qquad \text{as } t \to 0^+.$$

Thus by Lemma 4.4 and (5.1)

$$\max_{x\in\overline{\Omega}_{k+1}} u(x,t) = o\left(\left(\frac{1}{\sqrt{t}}\right)^{\frac{n^2}{n+2}\lambda}\right) \qquad \text{as } t\to 0^+$$

which clearly implies (2.6). ☐

Proof of Theorem 2.3. Since $\lambda > \frac{n+2}{n}$ and $\varphi(t)\to 0^+$ as $t\to 0^+$ there exists a sequence $\{T_j\}\subset\mathbb{R}$ such that $0 < 4T_{j+1} < T_j < \frac{1}{2}$,

$$\sum_{j=1}^{\infty}\varepsilon_j < \infty \qquad \text{where } \varepsilon_j = \sqrt{\varphi(T_j)},$$

and

$$0 < r_j < T_j/2 \qquad \text{where } r_j = T_j^{\frac{n\lambda}{n+2}}.$$

Let

$$M = \min_{\overline{\mathcal{P}_{1/2}(0,1)}} \Phi$$

where $\mathcal{P}_r(x,t)$ is defined by (4.9). Then $M>0$ and

$$\min_{\overline{\mathcal{P}_{T_j/2}(0,T_j)}} \Phi = M/T_j^{n/2}. \tag{5.5}$$

For the rest of this proof the variables (x,t) and (ξ,τ) (resp. (y,s) and (η,ζ)) will be related by

$$x=\sqrt{r_j}\xi,\ t=T_j+r_j\tau \qquad (\text{resp. } y=\sqrt{r_j}\eta,\ s=T_j+r_j\zeta).$$

Under this change of variables,

$$(y,s)\in\mathcal{P}_{r_j}(0,T_j) \text{ if and only if } (\eta,\zeta)\in\mathcal{P}_1(0,0).$$

Let $\psi:\mathbb{R}^n\times\mathbb{R}\to[0,1]$ be a C^∞ function whose support is $\overline{\mathcal{P}_1(0,0)}$. Define $\psi_j:\mathbb{R}^n\times\mathbb{R}\to[0,1]$ by

$$\psi_j(y,s)=\psi(\eta,\zeta).$$

Then the support of ψ_j is $\overline{\mathcal{P}_{r_j}(0,T_j)}$ and

$$\iint_{\mathbb{R}^n\times\mathbb{R}}\psi_j(y,s)\,dy\,ds = \iint_{\mathbb{R}^n\times\mathbb{R}}\psi(\eta,\zeta)r_j^{\frac{n}{2}+1}d\eta\,d\zeta = r_j^{\frac{n+2}{2}} I$$

where

$$I=\iint_{\mathbb{R}^n\times\mathbb{R}}\psi(\eta,\zeta)\,d\eta\,d\zeta > 0.$$

Let

$$f=\sum_{j=1}^{\infty}M_j\psi_j \qquad \text{where } M_j=\frac{\varepsilon_j}{r_j^{\frac{n+2}{2}}}.$$

Since the functions ψ_j have disjoint supports, $f \in C^\infty((\mathbb{R}^n \times \mathbb{R})\backslash\{0,0\})$. Also

$$\iint_{\mathbb{R}^n\times\mathbb{R}} f(y,s)\,dy\,ds = \sum_{j=1}^{\infty} M_j \iint_{\mathbb{R}^n\times\mathbb{R}} \psi_j(y,s)\,dy\,ds = I\sum_{j=1}^{\infty} M_j r_j^{\frac{n+2}{2}} = I\sum_{j=1}^{\infty}\varepsilon_j < \infty.$$

Thus the functions $u, v : \mathbb{R}^n \times \mathbb{R} \to [0,\infty)$ defined by

$$\begin{aligned} u(x,t) &= \iint_{\mathbb{R}^n\times\mathbb{R}} \Phi(x-y,t-s)f(y,s)\,dy\,ds \\ v(x,t) &= \frac{1}{M}\Phi(x,t) \end{aligned}$$

are C^∞ on $\mathbb{R}^n \times \mathbb{R}\backslash\{(0,0)\}$ and they clearly satisfy $(2.8)_2$ and (2.10).

For $(x,t) \in \overline{\mathcal{P}_{r_j}(0,T_j)}$ we have

$$\begin{aligned} u(x,t) &\geq \iint_{\mathcal{P}_{r_j}(0,T_j)} \Phi(x-y,t-s)M_j\psi_j(y,s)\,dy\,ds \\ &= \frac{\varepsilon_j}{r_j^{n/2}} \iint_{\mathcal{P}_1(0,0)} \Phi(\xi-\eta,\tau-\zeta)\psi(\eta,\zeta)\,d\eta\,d\zeta. \end{aligned}$$

Thus, letting

$$J = \iint_{\mathcal{P}_1(0,0)} \Phi(-\eta,-\zeta)\psi(\eta,\zeta)\,d\eta\,d\zeta > 0$$

we find that

$$u(0,T_j) \geq \frac{\varepsilon_j J}{r_j^{n/2}} = \frac{\sqrt{\varphi(T_j)}J}{T_j^{\frac{n^2\lambda}{2(n+2)}}} >> \frac{\varphi(T_j)}{T_j^{\frac{n^2\lambda}{2(n+2)}}} \quad \text{as } j \to \infty$$

which proves (2.9).

Also, for $(x,t) \in \mathcal{P}_{r_j}(0,T_j)$, it follows from (5.5) that

$$\begin{aligned} Hu(x,t) &= f(x,t) = M_j\psi_j \leq M_j \\ &= \frac{\varepsilon_j}{r_j^{\frac{n+2}{2}}} = \frac{\varepsilon_j}{T_j^{\frac{n\lambda}{2}}} \leq \left(\frac{1}{T_j^{n/2}}\right)^{\lambda} \\ &\leq \left(\frac{1}{M}\Phi(x,t)\right)^{\lambda} = v(x,t)^{\lambda} \end{aligned}$$

which yields $(2.8)_1$. □

Proof of Theorem 2.4. Define

$$p := \frac{\lambda+1}{\lambda\sigma-1} \quad \text{and} \quad q := \frac{\sigma+1}{\lambda\sigma-1}.$$

Then

$$\frac{1}{p} - \frac{2}{n} = \frac{\lambda}{\lambda+1}\left[\sigma - \left(\frac{2}{n} + \frac{n+2}{n\lambda}\right)\right].$$

Thus by (2.11)

$$0 < q \leq p < n/2. \tag{5.6}$$

Also

$$\lambda q = p+1 \quad \text{and} \quad \sigma p = q+1. \tag{5.7}$$

Let $\{T_j\} \subset (0,1)$ be a sequence such that $T_j \to 0$ as $j \to \infty$. Define $w_j, z_j : (-\infty, T_j) \to (0,\infty)$ by

$$w_j(t) = (T_j - t)^{-p} \quad \text{and} \quad z_j(t) = (T_j - t)^{-q}.$$

Then by (5.6) and (5.7), we have for $0 \le t < T_j$ that

$$w_j(t) \ge z_j(t), \quad w_j'(t) \ge z_j'(t), \quad w_j'(t) = p z_j(t)^\lambda, \quad z_j'(t) = q w_j(t)^\sigma. \tag{5.8}$$

Choose $t_j \in (0, T_j)$ such that $w_j(t_j) = t_j^{-n/2}$. Then

$$\frac{T_j}{t_j} - 1 = t_j^{\frac{n}{2p}-1} \to 0 \quad \text{as } j \to \infty \tag{5.9}$$

by (5.6).

Choose $a_j \in (t_j, T_j)$ such that $z_j(a_j) > j\varphi(a_j)$. Then

$$\frac{z_j(a_j)}{\varphi(a_j)} \to \infty \quad \text{as} \quad j \to \infty. \tag{5.10}$$

Let $h_j(s) = \sqrt{4(a_j - s)}$ and $H_j(s) = \sqrt{4(a_j + \varepsilon_j - s)}$ where $\varepsilon_j > 0$ satisfies

$$a_j + 2\varepsilon_j < T_j, \quad t_j - \varepsilon_j > t_j/2, \quad w_j(t_j - \varepsilon_j) > \frac{w_j(t_j)}{2}, \quad \text{and} \quad z_j(t_j - \varepsilon_j) > \frac{z_j(t_j)}{2}. \tag{5.11}$$

Define

$$\begin{aligned} \omega_j &= \{(y,s) \in \mathbb{R}^n \times \mathbb{R} \colon \ |y| < h_j(s) \quad \text{and} \quad t_j < s < a_j\} \\ \Omega_j &= \{(y,s) \in \mathbb{R}^n \times \mathbb{R} \colon \ |y| < H_j(s) \quad \text{and} \quad t_j - \varepsilon_j < s < a_j + \varepsilon_j\}. \end{aligned}$$

By taking a subsequence, we can assume the sets Ω_j are pairwise disjoint.

Let $\chi_j \colon \ \mathbb{R}^n \times \mathbb{R} \to [0,1]$ be a C^∞ function such that $\chi_j \equiv 1$ in ω_j and $\chi_j \equiv 0$ in $\mathbb{R}^n \times \mathbb{R} \setminus \Omega_j$. Define $f_j, g_j, u_j, v_j \colon \mathbb{R}^n \times \mathbb{R} \to [0,\infty)$ by

$$f_j(y,s) = \chi_j(y,s) w_j'(s), \quad g_j(y,s) = \chi_j(y,s) z_j'(s)$$

$$u_j(x,t) = \iint_{\mathbb{R}^n \times \mathbb{R}} \Phi(x-y, t-s) f_j(y,s)\, dy\, ds$$

and

$$v_j(x,t) = \iint_{\mathbb{R}^n \times \mathbb{R}} \Phi(x-y, t-s) g_j(y,s)\, dy\, ds.$$

Then u_j and v_j are C^∞ and

$$\begin{aligned} &Hu_j = f_j, \quad Hv_j = g_j \quad && \text{in } \mathbb{R}^n \times \mathbb{R} \\ &u_j = v_j = 0 && \text{in } \mathbb{R}^n \times (-\infty, 0) \end{aligned} \tag{5.12}$$

where $Hu = u_t - \Delta u$ is the heat operator.

By (5.8) and Theorem 3.5 we have

$$\begin{aligned}\left\| \iint_{\Omega_j\setminus\omega_j} \Phi(x-y,t-s)z_j'(s)\,dy\,ds\right\|_{L^\infty(\mathbb{R}^n\times(0,1))} &\le \left\| \iint_{\Omega_j\setminus\omega_j} \Phi(x-y,t-s)w_j'(s)\,dy\,ds\right\|_{L^\infty(\mathbb{R}^n\times(0,1))}\\ &\le C_n\|w_j'(s)\|_{L^{n+2}(\Omega_j\setminus\omega_j)}\\ &\le z_j(t_j)\le w_j(t_j) \qquad (5.13)\end{aligned}$$

provided we decrease ε_j if necessary.

Also, for $(x,t)\in\Omega_j$ we have $|x|\le\sqrt{4(T_j-t_j)}$ by (5.11); and thus using (5.11) again we obtain

$$\max_{(x,t)\in\Omega_j}\frac{|x|^2}{t}\le\frac{4(T_j-t_j)}{t_j-\varepsilon_j}\le\frac{8(T_j-t_j)}{t_j}\to 0 \quad \text{as} \quad j\to\infty \qquad (5.14)$$

by (5.9). Hence there exists a positive number M, independent of j, such that for all $(x,t)\in\Omega_j$ we have

$$M\Phi(x,t)\ge 2/t_j^{n/2}=2w_j(t_j)\ge 2z_j(t_j). \qquad (5.15)$$

In order to obtain a lower bound for u_j and v_j in Ω_j, note first that for $t_j-\varepsilon_j\le s\le t\le a_j+\varepsilon_j$ and $|x|\le H_j(t)$ we have

$$\begin{aligned}\int_{|y|<H_j(s)}\Phi(x-y,t-s)\,dy &= \frac{1}{\pi^{n/2}}\int_{|z-\frac{x}{\sqrt{4(t-s)}}|<\frac{H_j(s)}{\sqrt{4(t-s)}}} e^{-|z|^2}dz \qquad (5.16)\\ &\ge \frac{1}{\pi^{n/2}}\int_{|z-\frac{H_j(s)e_1}{\sqrt{4(t-s)}}|<\frac{H_j(s)}{\sqrt{4(t-s)}}} e^{-|z|^2}dz \quad \text{where } e_1=(1,0,\dots,0) \qquad (5.17)\\ &\ge \alpha_n \qquad (5.18)\end{aligned}$$

where

$$\alpha_n:=\frac{1}{\pi^{n/2}}\int_{|z-e_1|<1}e^{-|z|^2}\,dz\in(0,1). \qquad (5.19)$$

Some of the steps in the above calculation need some explanation. Equation (5.16) is obtained by making the change of variables $z=\frac{x-y}{\sqrt{4(t-s)}}$. Since $|x|\le H_j(t)\le H_j(s)$, the center of the ball of integration in (5.16) is closer to the origin than the center of the ball of integration in (5.17). Thus, since the integrand $e^{-|z|^2}$ is a decreasing function of $|z|$, we obtain (5.17). Since $H_j(s)\ge\sqrt{4(t-s)}$, the ball of integration in (5.17) contains the ball of integration in (5.19) and hence inequality (5.18) holds.

Using (5.18) and (5.19), we find for $(x,t)\in\Omega_j$ that

$$\begin{aligned}\iint_{\Omega_j}\Phi(x-y,t-s)w_j'(s)\,dy\,ds &= \int_{t_j-\varepsilon_j}^{t} w_j'(s)\left(\int_{|y|<H_j(s)}\Phi(x-y,t-s)\,dy\right)ds\\ &\ge \alpha_n(w_j(t)-w_j(t_j-\varepsilon_j))\ge\alpha_n w_j(t)-w_j(t_j)\end{aligned}$$

and similarly

$$\iint_{\Omega_j}\Phi(x-y,t-s)z_j'(s)\,dy\,ds\ge\alpha_n z_j(t)-z_j(t_j).$$

It therefore follows from (5.13) that for $(x,t) \in \Omega_j$ we have

$$\begin{aligned} u_j(x,t) &\geq \iint_{\omega_j} \Phi(x-y,t-s) w_j'(s)\,dy\,ds \\ &= \iint_{\Omega_j} \Phi(x-y,t-s) w_j'(s)\,dy\,ds - \iint_{\Omega_j \setminus \omega_j} \Phi(x-y,t-s) w_j'(s)\,dy\,ds \\ &\geq \alpha_n w_j(t) - 2w_j(t_j) \end{aligned} \tag{5.20}$$

and similarly

$$v_j(x,t) \geq \alpha_n z_j(t) - 2z_j(t_j).$$

Also,

$$\begin{aligned} \iint_{\mathbb{R}^n \times \mathbb{R}} f_j(y,s)\,dy\,ds &\leq \iint_{\Omega_j} w_j'(s)\,dy\,ds \\ &\leq p \int_0^{T_j} (T_j - s)^{-(p+1)} \left(\int_{|y|<\sqrt{4(T_j-s)}} dy \right) ds \\ &= \omega_n p \int_0^{T_j} (T_j - s)^{-(p+1)} (4(T_j-s))^{n/2} ds \\ &= 4^{n/2} \omega_n p \int_0^{T_j} (T_j - s)^{n/2-p-1} ds \\ &= 4^{n/2} \omega_n p \int_0^{T_j} \tau^{n/2-p-1}\,d\tau \\ &\to 0 \quad \text{as } j \to \infty \end{aligned}$$

by (5.6). We consequently obtain from (5.8) that

$$\iint_{\mathbb{R}^n \times \mathbb{R}} \sum_{j=1}^{\infty} g_j(y,s)\,dy\,ds \leq \iint_{\mathbb{R}^n \times \mathbb{R}} \sum_{j=1}^{\infty} f_j(y,s)\,dy\,ds < \infty$$

provided we take a subsequence if necessary. Hence the functions $u, v \colon (\mathbb{R}^n \times \mathbb{R}) \setminus \{(0,0)\} \to [0,\infty)$ defined by

$$\begin{aligned} u(x,t) &= 1 + M\Phi(x,t) + \sum_{j=1}^{\infty} u_j(x,t) \\ v(x,t) &= 1 + M\Phi(x,t) + \sum_{j=1}^{\infty} v_j(x,t) \end{aligned}$$

are C^∞ and by (5.12) we have

$$\begin{aligned} Hu &= \sum_{j=1}^{\infty} f_j, \quad & Hv &= \sum_{j=1}^{\infty} g_j \qquad &&\text{in } (\mathbb{R}^n \times \mathbb{R}) \setminus \{(0,0)\} \\ u &= 0, & v &= 0 &&\text{in } \mathbb{R}^n \times (-\infty, 0). \end{aligned} \tag{5.21}$$

Also, for $(x,t) \in \Omega_j$ we have by (5.20) and (5.15) that

$$\begin{aligned} u(x,t) &\geq M\Phi(x,t) + u_j(x,t) \\ &\geq M\Phi(x,t) + (\alpha_n w_j(t) - 2w_j(t_j)) \\ &\geq \alpha_n w_j(t) \end{aligned} \tag{5.22}$$

and similarly

$$v(x,t) \geq \alpha_n z_j(t). \tag{5.23}$$

Thus by (5.8) and (5.10) we have

$$\begin{aligned} \min\left\{\frac{u(0,a_j)}{\varphi(a_j)}, \frac{v(0,a_j)}{\varphi(a_j)}\right\} &\geq \min\left\{\frac{\alpha_n w_j(a_j)}{\varphi(a_j)}, \frac{\alpha_n z_j(a_j)}{\varphi(a_j)}\right\} \\ &= \frac{\alpha_n z_j(a_j)}{\varphi(a_j)} \to \infty \quad \text{as } j \to \infty, \end{aligned}$$

and so u and v satisfy (2.13) and (2.14).

It also follows from (5.8), (5.21), (5.22) and (5.23) that for $(x,t) \in \Omega_j$ we have

$$\begin{aligned} Hu(x,t) &= f_j(x,t) \leq w_j'(t) = p z_j(t)^\lambda \leq p\left(\frac{v(x,t)}{\alpha_n}\right)^\lambda \\ Hv(x,t) &= g_j(x,t) \leq z_j'(t) = q w_j(t)^\sigma \leq q\left(\frac{u(x,t)}{\alpha_n}\right)^\sigma. \end{aligned} \tag{5.24}$$

Inequalities (5.24) also hold for $(x,t) \in (\mathbb{R}^n \times \mathbb{R}) \setminus \bigcup_{j=1}^{\infty} \Omega_j$ because $Hu = Hv = 0$ there by (5.21). We thus obtain inequalities (2.12) by scaling the independent variables x and t. ☐

Proof of Theorem 2.5. Theorem 2.5 follows from (and is actually the same as) Lemma 4.5(i). ☐

Proof of Theorem 2.6. Theorem 2.6 follows immediately from the conclusion (4.22) in Lemma 4.4. ☐
